A review of data published in the foreign press
(American, Canadian, etc.) on the simultaneous pro-
duction of phenol and acetone indicates that this
method is valued by the industry as perhaps the most
promising and profitable method for the production of
these products.

A literature search showed that yields up to 85% have been obtained with Cd-salt catalysts. An experimental study of the process via their dipotassium salts established that the optimum conditions are a temperature of 460°C, a reaction period of 1.5 hr, and an initial CO₂ pressure of at least 10 atm. A terephthalic acid yield of 73 or 74% of the theoretical can be obtained.

X-ray films (XX, Agfa Laue, and Agfa Texo) were
sensitive to electrons with energies 2 to 40 electron
volts. The Agfa Laue film was more sensitive than
the others to electrons with energies of 2 to 20 ev.
The relation of the densities to the electron energy
within the range of 2 to 40 electron volts is shown for
the films. Density has a minimum at 12 to 20 ev.
When the film is developed in a "sub-surface" devel-
oper, a minimum or an inflection point exists; the
density depends upon the length of irradiation time at
